HOW TO ORDER

TID-26-608/PAT 141 p PC\$6,00/MF\$3,00

When you indicate the method of payment, please note if a purchase order is not accompanied by payment, you will be billed an addition \$5.00 ship and bill charge. And please include the card expiration date when using American Express.

Normal delivery time takes three to five weeks. It is vital that you order by number

or your order will be manually filled, insuring a delay. You can opt for airmail delivery for a \$2.00 charge per item. Just check the Airmail Service box. If you're really pressed for time, call the NTIS Rush Order Service. (703) 557-4700. For a \$10.00 charge per item, your order will be airmailed within 48 hours. Or, you can pick up your order in the Washington Information Center & Bookstore or at our Springfield Operations Center within 24 hours for a \$6.00 per item charge.

You may also place your order by telephone or TELEX. The order desk number is (703) 557-4650 and the TBLEX number is 89-9405.

Whenever a foreign sales price is NOT specified in the listings, all foreign buyers must add the following charges to each order: \$2.50 for each paper copy; \$1.50 for each microfiche; and \$10.00 for each Published Search.

Thank you for your interest in NTIS. We appreciate your order.

SUMMARY

This report covers structural tests conducted at the U. S. Army Engineer Research and Development Laboratories to evaluate rigid foam plastics shelters.

Based on the test results, it is concluded that:

- a. It is feasible to fabricate structural members by using fiberglass-polyester skins over either polyurethane core or paper honeycomb core.
- b. Bonding between the skins and the core material is of utmost importance in stressed-skin design.

I. INTRODUCTION

- 1. <u>Subject.</u> This report covers structural tests conducted at the U. S. Army Engineer Research and Development Laboratories (USAERDL) to evaluate rigid foam plastics shelters.
- 2. Background. Military prefabricated buildings are normally produced in a fabricating plant and shipped to worldwide locations for erection and use. The logistic problems of transporting heavy tonnage and large volume of bulky building panels lent emphasis to investigation of rigid foam plastics as a building material. The foam plastics materials offer a solution to the problems by providing a worldwide-use building that is considerably lighter in weight and is fabricated of material expanded approximately 30 times its original volume on the site, thus reducing shipping volume manyfold. The state-of-the-art in foaming plastics has shown the concept of shipping drums of liquid resin and fabricating plastics buildings in remote areas to be feasible.

Paper honeycomb is being investigated in conjunction with the rigid foam plastics buildings project as a means of adding reinforcement, where needed, to the foam plastics material. When used as stressed-skin panel core material, paper honeycomb offers approximately the same logistic advantage as foam plastics. The paper honeycomb is procurable in prefabricated folded slices which expand 20 to 30 times the shipping volume. A high-strength, durable building panel is produced when filter-glass skins are bonded to the surfaces of the expanded paper. The economy and strength-weight ratio attributes are as high as or higher than those of any other known panel core material; therefore, paper honeycomb is very desirable for field fabrication.

II. INVESTIGATION

3. Reinforced Fiberglass Plastics Beams. Three reinforced fiberglass plastics beams were fabricated with polyurethane foam plastics core material and tested as stringer supports for foam plastics floor

sections. The beams were designed for supporting a uniform floor load of 50 pounds per square foot when spaced on 3-foot centers with a span of approximately 12 feet. Beams 1 and 2 were cast in a 16-foot-long mold; the core for Beam 3 was cast by slip mold technique and was 7 feet 2-3/4 inches long. A short mold which moved vertically on a fixed rail was used for the slip mold technique of fabrication. The mold was approximately 2 feet long and was open at the top and bottom. Resin components poured in the top of the mold expanded, set, and extruded as a beam from the bottom of the mold. Four rolls of paper, fixed at the top of the mold with the free end of the paper passing through the mold and secured at the rail base platform, supplied the mold lining necessary to prevent adherence of the foam to the moving mold. Beam 1 was fabricated by casting the polyurethane core, removing the core from the mold, then spraying the fiberglass skin. Beam 2 (Fig. 1) was fabricated by spraying the fiberglass skin on the inner surfaces of the mold, then assembling the mold and pouring the polyurethane core to complete the beam. A fibergiass skin was also sprayed over the core of Beam 3.

H5177

Fig. 1. Reinforced fiberglass plastics Beam 2.

The effective section modulus of each beam was computed and is shown in Appendix B, Exhibit 1.

Exhibits 2, 3, and 4 of Appendix B show the test setup and location of strain gages for each beam. Beam 2 supported twice as much load as Beam 1 and did not fail until a total load equivalent to a uniform floor load of 118.37 pounds per square foot was applied (Fig. 2). This was to be expected, however, since the section modulus of Beam 2 was much greater than that of Beam 1 (Appendix B, Exhibit 1). Exhibits 5, 6, and 7 of Appendix B show the applied loads, resulting moments, and corresponding measured stresses for each beam.

H5219

Fig. 2. Test setup for applying uniform load to reinforced plastics beams (Beam 2).

Results of the tests for the three beams are summarized in Table I.

After failure of the beams (Figs. 3 and 4), four composite specimens were cut from each beam (Figs. 5 and 6) and subjected to additional laboratory testing to determine the physical properties of each specimen. Results of these tests are presented in Appendix C.

4. <u>Honeycomb Floor Panels</u>. Several different floor concepts were considered, and honeycomb floor panels were selected because they offer one of the more feasible means of providing a floor of sufficient strength for the 16-foot-wide building.

The floor growth (arching effect) in the Greenland snow tunnels, amounting to approximately 2 inches per year, presented a problem in the design of the floor. Experience has revealed that the best method of dealing with the annual rise in the tunnel floor is to provide lateral floor panels with a simple beam span. Supporting stringers run longitudinally with the

building, near the outside walls. With this type of footing, the floor can be supported a sufficient distance off the tunnel floor to allow for several years of tunnel floor growth before it becomes necessary to raise the building. Also, the building can be more easily raised and shimmed in increments, when necessary.

The paper honeycomb core material was procured and shipped to the field in the unexpanded form. The honeycomb core was an untreated paper (99 pounds per ream) with 3/4-inch cells. The field expansion ratio over the shipping volume was over 20 to 1, which provided a logistic advantage similar to that of polyurethane foam. Fabrication of a honeycomb panel consisted of saturating woven fiberglass cloth with epoxy resin, expanding the honeycomb core material, and placing the saturated fiberglass sheets on the core material. The final operation consisted of placing "sandwich" panel in a vacuum bag and allowing the panel to cure under vacuum (5 to 10 inches of mercury) to insure a good bond between the paper honeycomb core and the fiberglass skins. The field fabrication setup for a 3- by 16-foot honeycomb panel was made by two men in approximately 1 hour.

Tests were conducted on 4-, 5-, and 6-inch-thick panels to determine the most suitable panel and span to support a design live load of 50 pounds per square foot without exceeding a deflection ratio of 1/240 of the unsupported span. To shorten the span, it was determined that the huilding could cantilever approximately 1 foot over each outside stringer without any detrimental effects, since the buildings would not be subjected to any snow or wind load forces in the Greenland snow tunnels. Thus, the clear floor span was reduced to 12 feet by using two 1-foot-wide stringer supports. The effective section modulus of each size panel was computed as shown in Appendix B, Exhibit 8.

One 4-inch-thick, one 5-inch-thick, and three 6-inch-thick honeycomb panels were strain gaged and tested to failure. Expanded polystyrene beads were added to one of the 6-inch-thick panels in an effort to arrive at an expedient field method of adding insulation and improving the thermal conductivity quality of the panels. Exhibits 9 through 13 of Appendix B show the test setup and location of strain gager for each panel. Exhibits 14 through 18 show the applied loads, resulting moments, and corresponding measured stresses. Panel 4 was tested on a 16-foot simple beam span and supported a greater load than any of the panels tested. Failure did not occur until a total load equivalent to a uniform floor load of 122 pounds per square foot was applied (Figs. 7 and 8). Results of the strain gage tests for the five panels are summarized in Table II.

Speciments were cut from honeycomb Panel 3 and analyzed by the USAERDL Materials Branch to determine physical properties of the woven fiberglass skin material. Results of these tests are presented in Appendix D.

5. Experimental Greenland Building. Structural tests were performed on the building to determine the wind and snow load capacity, the

location of critical stresses, and the maximum deflection under loaded conditions. To simulate the most severe condition of loading, the building was tested without benefit of end walls. Figures 9 and 10 show the test setup for application of simulated wind and snow loads, respectively. The design wind pressures and resulting wind loads for a 9-foot test module were computed and are shown in tabular form in Exhibits 19 and 20 of Appendix B. Wind load forces were computed in accordance with Metal Building Manufacturers Association Standards which are equally applicable to all types of construction.

Simulated wind loads were applied by means of ratchet chain hoists, and simulated snow loads were applied by means of sandbags placed on the roof. Electrical strain gages were placed as shown in Exhibits 21 and 22 of Appendix B to determine the stresses under each increment of loading. A maximum simulated wird load equivalent to a 100-mile-perhour wind was being applied when failure occurred. The test module did not collapse; however, the skin ruptured to the extent that additional load could not be sustained. Exhibit 23 of Appendix B shows the tabulated stresses and deflections produced by the simulated wind load test. A new 12-foot shelter test module was erected for the snow load tests, and roof loads were applied in increments until a maximum short-term roof load of 50 pounds per square foot was applied without failure occurring. Exhibit 24 of Appendix B shows each increment of loading and a tabulation of the resulting stresses. After the strain data were obtained, the test module was allowed to remain under 20-pound-per-square-foot simulated snow load for 72 hours and under 20- and 40-pound-per-square-foot loads for 24 hours to determine the amount of creep or set occurring under sustained load conditions. Appreciable set was not measured until the 40-pound-persquare -foot load was removed, and failure did not occur until the shelter retained a 50-pound-per-square-foot load for 4 hours (Fig. 11). Exhibit 25 of Appendix B shows the deflection and set resulting from the sustained conditions of loading.

III. DISCUSSION

6. Reinforced Fiberglass Plastics Beams. When the plastics beams were designed, the foam core was considered as being noneffective in contributing to the load-carrying capacity. However, a comparative analysis of measured stresses versus theoretical stresses revealed that the theoretical stresses were considerably higher. This discrepancy could be

J3224 Fig. 9. Test setup for application of simulated wind forces on shelter test module.

H12355 Fig. 10. Test setup for application of simulated snow load on shelter test module.

J3665

Fig. 11. Failure of shelter test module under 50-pound-per-square-foot sustained simulated snow load.

partially due to variations in thickness of the laminates as reported in Appendix C (Materials Branch Report 9289-1); however, it is more likely that the foam core section is slightly effective (from 5 to 10 percent) in producing a composite beam effect which contributes to the flexural load-supporting capacity of the beam. Additional testing is planned, using homogeneous premolded fiberglass sheets as panel skins to study the composite beam theory with a foam plastics core material.

7. Honeycomb Floor Panels. Although the strength of the 6-inch-thick, 16-foot-long honeycomb panel was found to be more than 2½ times the strength required to support the 50-pound-per-square-foot design floor load, the deflection of the panel is so great that it cannot be considered as a simple beam floor member unless each end of the panel is cantilevered approximately 2 feet over the floor-supporting stringers. This arrangement permits negative moment for 2.35 feet on each end of the panel and reduces the critical positive moment deflection producing length from 16 feet to 11.30 feet. At 50-pound-per-square-foot floor load, the total deflection in 6-inch-thick Panel 4 was interpolated to be 2.59 inches when the panel was

supported on a 16-foot span. The maximum allowable deflection for floors in prefabricated military buildings has been established at 1/240 of the span (0.80 inch) for a 16-foot-wide building. A rerun of the test of the 6-inch-thick, 16-foot-long panel with a clear span of 12 feet and a uniform load of 50 pounds per square foot produced a maximum deflection of 0.83 inch, which is considered acceptable.

Test of 6-inch-thick Panel 5 revealed that a loss in structural capacity occurred when the honeycomb core of the panel was partially filled with polystyrene beads. Intermingling of the beads between the epoxy resin skin and the paper honeycomb core prevented a good bond of the fiberglass skins to the core material. The top and bottom skins were bonded in one operation, and it is believed that the problem could be alleviated by bonding the skins in two operations. Thus, the bottom skin would be bonded to the honeycomb core and allowed to cure, the beads would be added, then the top skin would be bonded to the core. Calculations show that a 6-inch-thick honeycomb panel with 2 inches of polystyrene beads and a 2-inch-thick polyurethane panel with fiberglass skins have approximately the same U factor. One of the most serious deficiencies in the use of polystyrene beads on the site is the short shelf life of the beads in the unexpanded state. This shelf life under optimum conditions has been determined to be approximately 1 year. Other types of insulation material that have a longer shelf life and can be expanded on the site are being investigated in an effort to improve the thermal conductivity of honeycomb material.

The paper honeycomb material used for these tests and for the Camp Century, Greenland, building was of the intreated type which was suitable for the Greenland snow tunnels where no moisture problems exist. For an all environmental building, however, it will be necessary to provide a core material that is resistant to moisture, fungi, bacteria, rodents, and so forth; and it is desirable that this be accomplished without the field heat-curing process required for phenolic-impregnated paper honeycomb. Therefore, investigations are being carried out with pretreated paper honeycomb and other honeycomb materials that can be expanded on the site and require no field heat-cure processing.

8. Experimental Greenland Building. The structural test results show that the most critical stresses on the shelter occur at the ridge under both wind (Gages 15 and 16) and snow load (Gages 13 and 14) conditions; however, the highest stresses (3.9 and 3.8 kips per square inch) were recorded under the 50-pound-per-square-foot simulated snow load test. The

H11775 Fig. 12. Polyurethane plastics building in the ice tunnel at Camp Tuto, Greenland.

Fig. 13. Polyurethane plastics building in a snow tunnel at Camp Century, Greenland.

H10889

Fig. 14. Interior of polyurethane plastics building at Camp Century, Greenland.

tests show that the thickness of the panel ribs should be increased approximately 1 inch in the ridge area. This would effect a more satisfactory distribution of stress and produce a shelter which could in all probability be rated for 40-pound-per-square-foot snow loads or 80-mile-per-hour winds with gusts up to 120 miles per hour (with proper tiedown arrangements) when erected with end walls such as the two buildings used for troop occupation tests in Greenland (Figs. 12 through 14).

IV. CONCLUSIONS

- 9. Conclusions. Based on the test results, it is concluded that:
- a. It is feasible to fabricate structural members by using fiberglass-polyester skins over either polyurethane core or paper noneycomb core.
- b. Bonding between the skins and the core material is of utmost importance in stressed-skin design.

b. Approach:

- (1) Engineer Research and development work will be performed by the technical staff of the Corps of Engineers with assistance from research and engineering staffs of commercial suppliers as needed.
- (2) Engineering research and studies will be undertaken in the following areas to determine the most suitable means of satisfying the overall military requirements:
- (a) Development of economical, lightweight, rigid foam plastic resins, including reinforced rigid foam plastics which can be foamed and stored in all environments.
 - (b) Portable field spraying equipment.
- (c) Techniques of foaming shelters and buildings in all environmental conditions.
- (d) Methods of internally reinforcing rigid plastic form for use in shelters and buildings where high snow and wind loads are encountered.
- (a) Development of structural design criteria for rigid form plastics including reinforced rigid form plastics.
- (3) Comprehensive engineering tests of pilot model shelter modeling and spraying equipment, including techniques, will be conducted to determine the general suitability and to determine necessary modifications prior to submittal for user tests. Drawing and purchase descriptions shall be modified to reflect the equipment passing the tests.
- (4) Service test equipment shall then be procured and furnished to the weepons systems or application for which the equipment was developed.
- (5) After all tests and necessary revisions of the equipment have been accomplished, complete drawings and specifications will be prepared and forwarded to the Chief of Engineers, together with recommendations regarding classification action on the equipment developed.
- c. Tasks: Not applicable
- d. Other information:
 - (1) Scientific Research: None
 - (2) References: None
- (3) Discussion:

 1 Agencies interested in this project in addition to the Corps of
 Engineers, with which liaison will be maintelned and which will be furnished coples of reports on the project ade USCONARC, Medical Corps, Quartermester Corps,

EXHIBIT "A"

TECHNICAL CHARACTERISTICS FOR RIGID FOAM PLASTIC SHELTERS

- 1. The rigid type shelters formed in the field by use of low density core materials shall consist of all weather units in all ranges of covered space provisions, including maint enance of vehicles, missile, and other mechanical/electrical equipment, command posts, air stations, fire direction centers, personnel housing, collective protection and other general purpose requirements.
- 2. Means shall be developed for fabrication of shelters under all environmental conditions as specified in AR 705-15.
- 3. Shelters shall be capable of being constructed for all climate operations to withstand steady winds of 60 miles per hour and to support snow loads of 20 pounds per square foot. Features shall be incorporated (in kit form if applicable) to permit the shelters to be used in areas where snow loads reach 40 pounds per square foot and wind loads correspond to velocities of 80 miles per hour with gusts of 120 miles per hour.
- 4. The shelters shall be made of the smallest possible number of components and component types, and be capable of easy handling and rapid erection by personnel within companies and battalions.
- 5. The shelters shall be compatible with chemical, biological, and radiological protection.
- 6. The shelters shall be durable, weatherproof and fire retardant. They shall not be subject to appreciable weather deterioration, or attack by insects, fungi, bacteria, or rodents.
- 7. Wearing surfaces, both exterior and interior, shall withstand normal barracks type use.
- 8. The completed system shall permit erection of variable length shelters.

- 9. Provisions shall be made in the design of the shelters for the installation of standard or fabricated on the site doors and windows located on both sides and/or ends.
- 10. The shelter equipment shall be lightweight and portable for field service, sufficiently rugged to withstand prolonged cross-country movement and transportation in Phase II of airborne operations. It shall be designed with maximum simplicity commensurate with intended performance and be capable of manufacture in quantity by modern fabrication methods.

EVALUATION OF GLASS REINFORCED PLASTIC SKIN ON EXPERIMENTAL PLASTIC BEAMS

Roport No:

£289-1

Requested by: Special Equipment Branch

Authority:

8F71-04-001-04

- 1. The purpose of this investigation was to determine the physical properties of the glass fiber reinforced plastic skins on some experimental plastic beams. The density of the foam core was to be determined where this showed a variation in structure. The beams were designated by the code la 1d and 2a 2d.
- 2. The beams were made in the Model Shop by spraying the inside of a mold with a polyester resin and glass fiber mixture and then pouring into the interior a polyurethane foam mixture. The excess foam was cut off and the open side then sprayed with the resin glass fiber mixture.
- 3. The properties of the skin laminate were determined in accordence with the following methods of Federal Specification L-P-406b, "Plastics, Organic: General Specifications, Test Methods":

Method No	Title of Method
1011	Tensile properties of plastics.
1021	Compressive properties of plastics.
1031	Flexural properties of plastics.
1041	Shear properties of plastics.
5011	Specific gravity by displacement of water.
7061	Resin in inorganic-lilled plastics.

The specific gravity of the foam was determined in accordance with Method No. 5012, specific gravity from weight and volume methods.

- that the glass content was extremely low; hence, low physical properties could be expected. This was found to be the case. Glass content ranged from 21.90 27.86 percent, tensile strength from 7,010 9,690 psi, compressive strength from 10,000 15,900 psi, flexural strength from 12,300 19,800 psi, and shear strength from 6,150 8,870 psi. The wide variation was probably due to large variations in thicknesses of the laminates and to uneven distribution of the glass fibers. It has been found possible to obtain laminates by the process used with as high as 50 percent glass. It would appear that the ratio of the resin to glass must be changed to accomplish this. Variation of the foam core was from 1.4 to 28 percent. In three of the panels, there was no difference at all. In a previous investigation, it was shown that the dispensing machine was at fault in that the components were improperly mixed.
- 5. It is concluded that the laminate comprising the skin has a low glass content and, hence, has low physical properties usually associated with low glass content. The foams in the panels varied in density from 1.4 to as high as 28 percent.
- 6. It is recommended that an attempt be made to upgrade the strength by using a higher ratio of glass to resin than was used in making the panels. Modifications to the existing machine for dispensing the foam should be made to obtain better uniformity, or else a better machine should be procured.

TEST PLASTIC PANEL ON HONEYCOME

Report No:

9506-1

Requested by: Special Equipment Branch

Authority: Project No. 8F71-04-001-04

- 1. The purpose of this work was to determine the same is indicate pressive strongth, florural modulus of elasticity, and goese or tent of a glass reinforced plastic sheet skin. The sheet was fabriced from grant-fiber Roveoloth and a laminating resin. It was the skin of a sandwich sestruction composed of a cardboard honeycomb supplied by the Special Equipment Branch.
- 2. For the flexure, tensile, and glass content tests, three eperamens each were out from the top and bottom of the plastic panel. Due to the variation in thickness of the panel, each specimen was sanded to approximately a uniform thickness. The proporties were determined according to methods listed in Federal Specification L-P-406b, "Plastics, Organic: General Specifications, Test Methods," dated 27 September 1961. Due to the small thickness, it was impossible to determine the compressive strength by ordinary means. It was estimated by the calculation of the penetration index.

Property

Test Mothed

Tensile Strength

Method 1011, with specimens cut from the

specification of figure 1011A.

Flaxural Modulus

Method 1031, with specimens cut from the

specification of figure 1031.

Glass Content

Method 7061, with specimens cut from the

pieces used for the flexure tests.

Compressive Strength

The specimen was a piece of the criginal

laminate.

Penatration Index

Method as described in USAERDL Technical Report 1683-TR, "Development of Nondestruc-

tive Tout for Plantics."

The results of the tests are listed in Table IV. 3.

The differences in values from the arbitrary too and bottom of the honeycomb are probably due to the variation in thickness of the lexibate. exerctional precedures. and the actual physical structure of the Roveclath • d -esin. The original levaluate was approximately 1/16 inch in thickness. and after sunding to a uniform thickness, it was about 1/02 inch thick. It we received that the portion of the lawinate zanded was pure resig. To check in validity of the compression results as estimated from the penetration index, the tensile strengths were calculated by use of the penetration index. 🤹 values compared favorably with the solval experimental values, so it can be assumed that the compression results are fairly accurate. The el as content reported was that of the test specimens because of the irrenuis by of the original laminate.

Upon consulting a fiberglass manual, it was found that tenelle Trangths of this type of laminate with the reported glass content were approximately 24,000 pai and compressive strongths were 22,000 psi.

Ŧ. It is concluded that:

The laminete is of low quality and strength and is highly at. variable in physical proporties.

b. The sanding operation makes the panel appear to be better structurally than it actually is.
